- Conclusion and outlook

Aim

The aim of this research is to establish a simulation tool that enables:

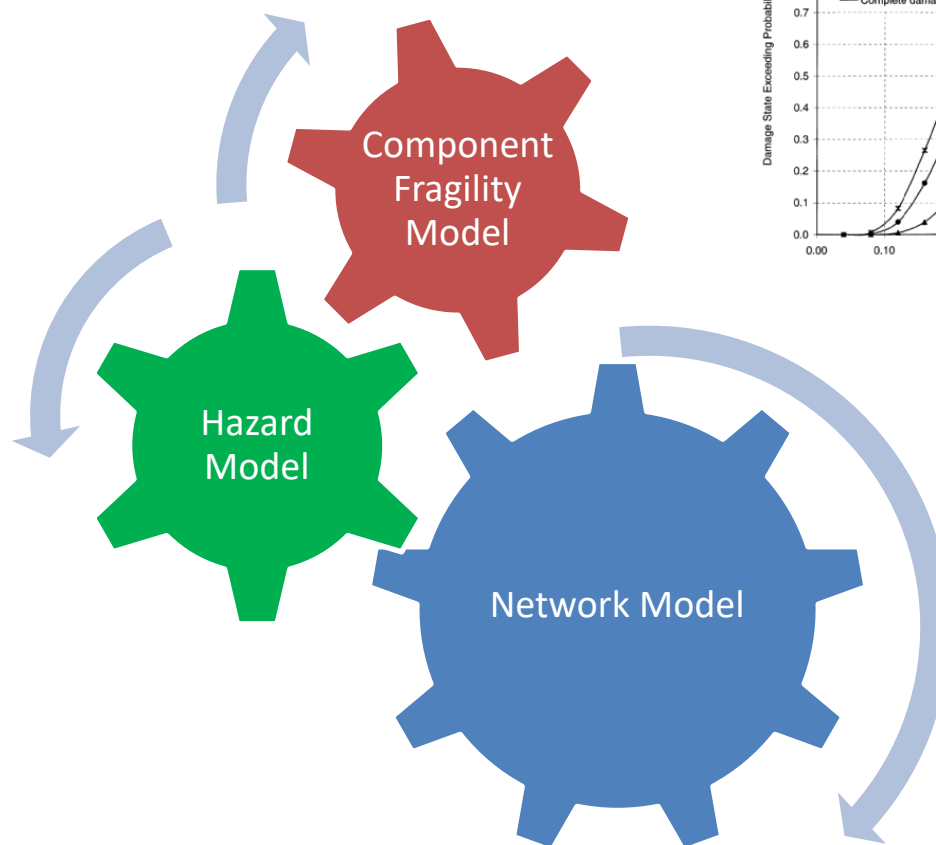

1. Power loss estimation
2. System resilience quantification
3. Informed investments

Outline

- Aim
- Approach
- Case study
- Conclusion and outlook

Approach

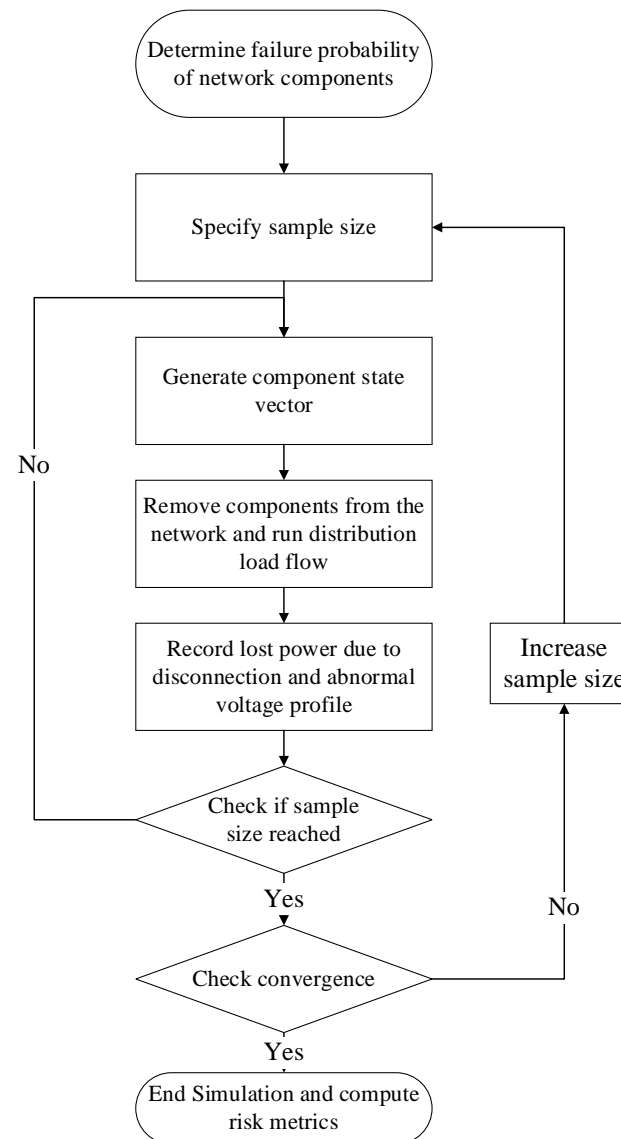

Approach

Substation – Circuit breakers,
disconnectors, bus bars transformer

Network – Bus bars, underground
cables, switches

Framework – Static

Variant – Dynamic, spatial-temporal
impact of extreme weather events

Approach -- Functionality metrics

Expected load not supplied:

$$E(P_{loss})$$

Load at risk:

$$VaR_{\alpha}(P_{loss}) = \min\{\gamma: P(P_{loss} \leq \gamma) \geq \alpha\}$$

Conditional load at risk:

$$CVaR_{\alpha}(P_{loss}) = E[P_{loss} | P_{loss} \geq VaR_{\alpha}(P_{loss})]$$

Outline

- Aim
- Approach
- **Case study**
- Conclusion and outlook

Case study -- Substation configuration

- Boolean logic
- Minimum cut set

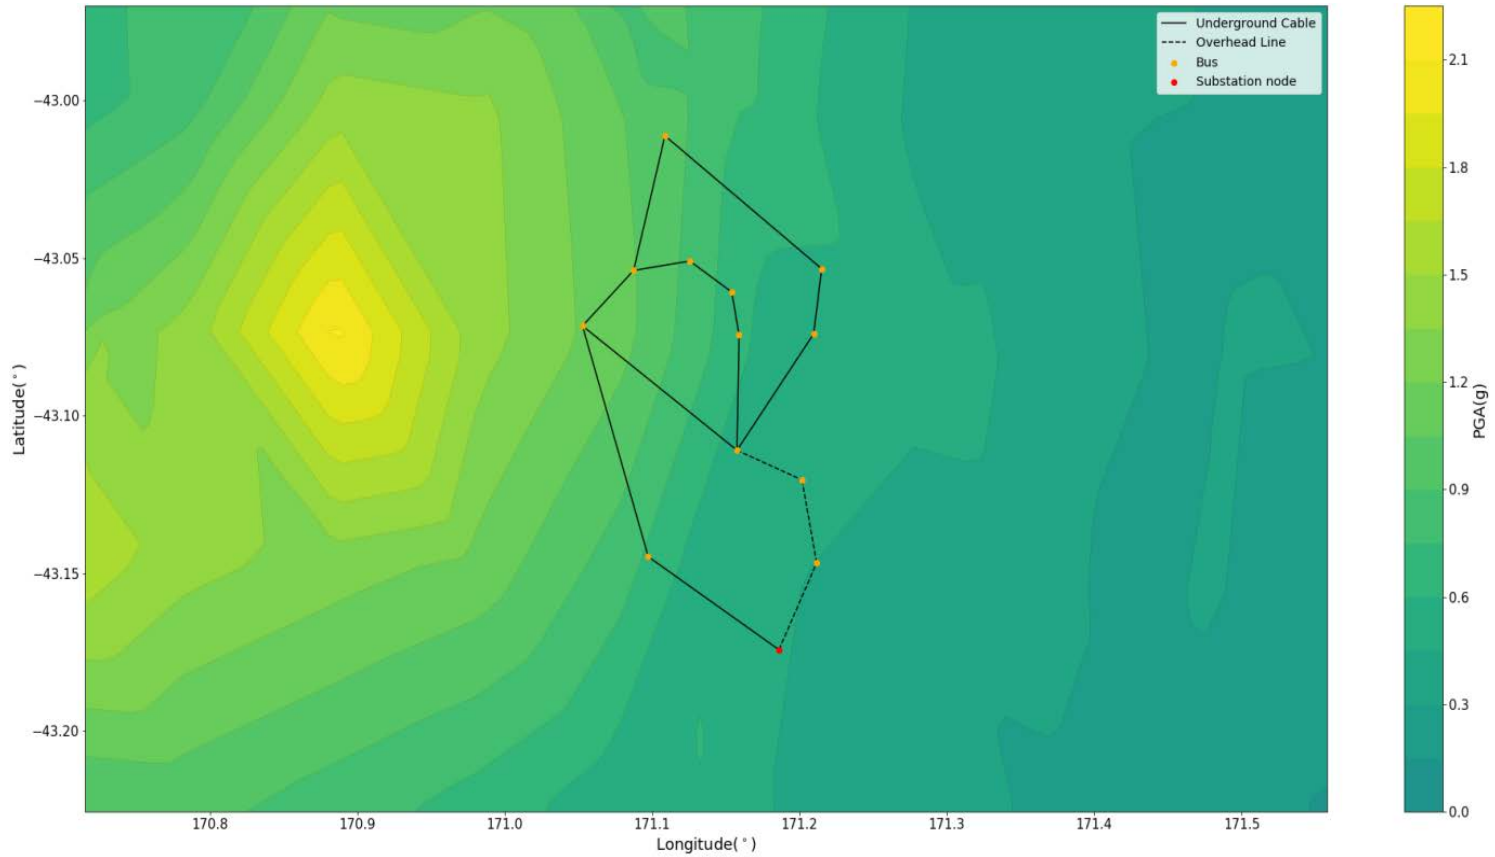

Case study -- Network configuration

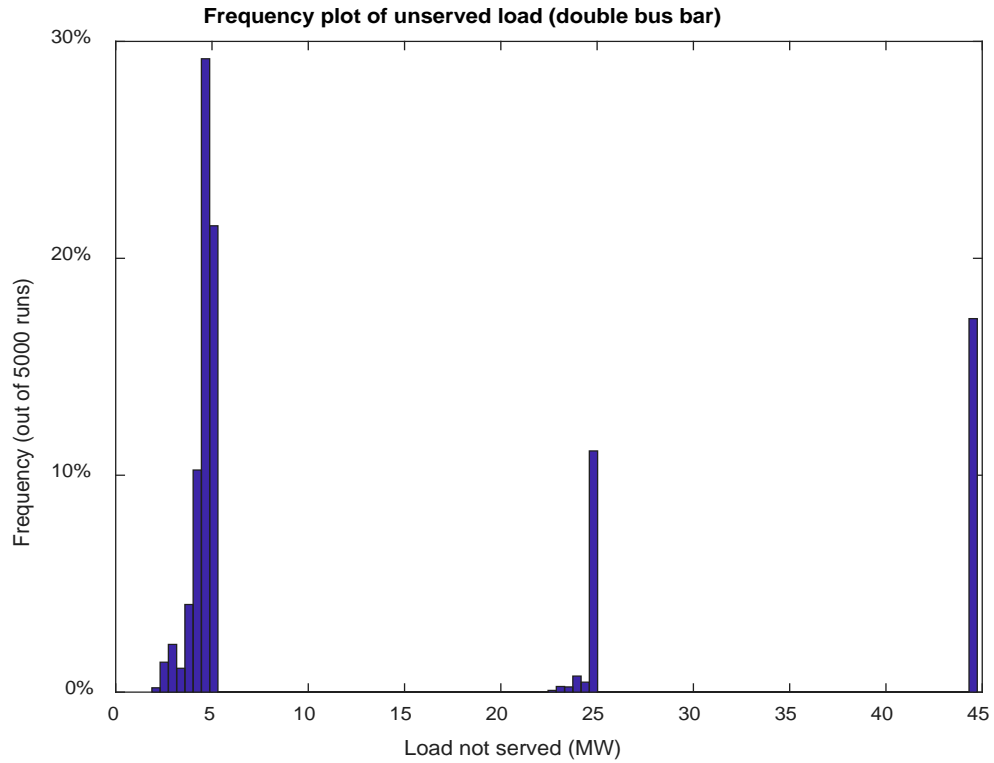

- Medium voltage distribution network supplying a small town and rural area
- Can be operated as either a radial or weakly meshed network by switching S1,S2,S3

Case study

Case study

Case study

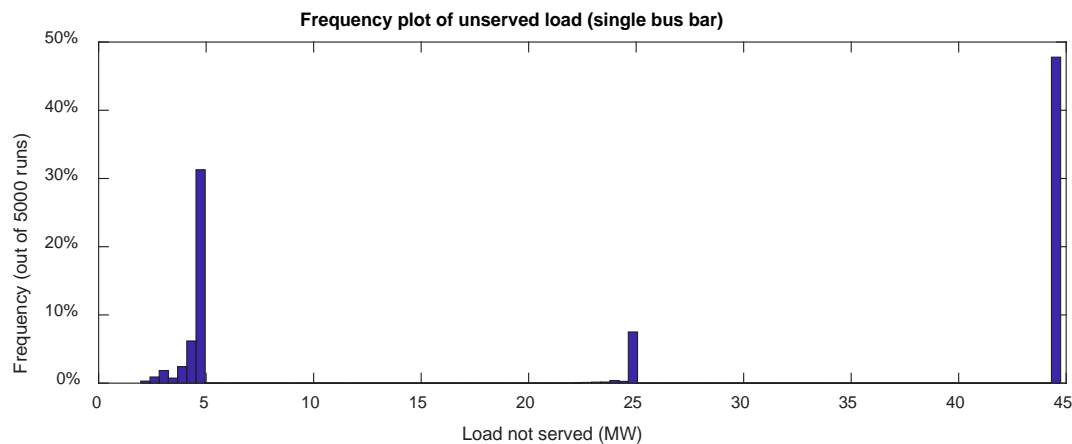

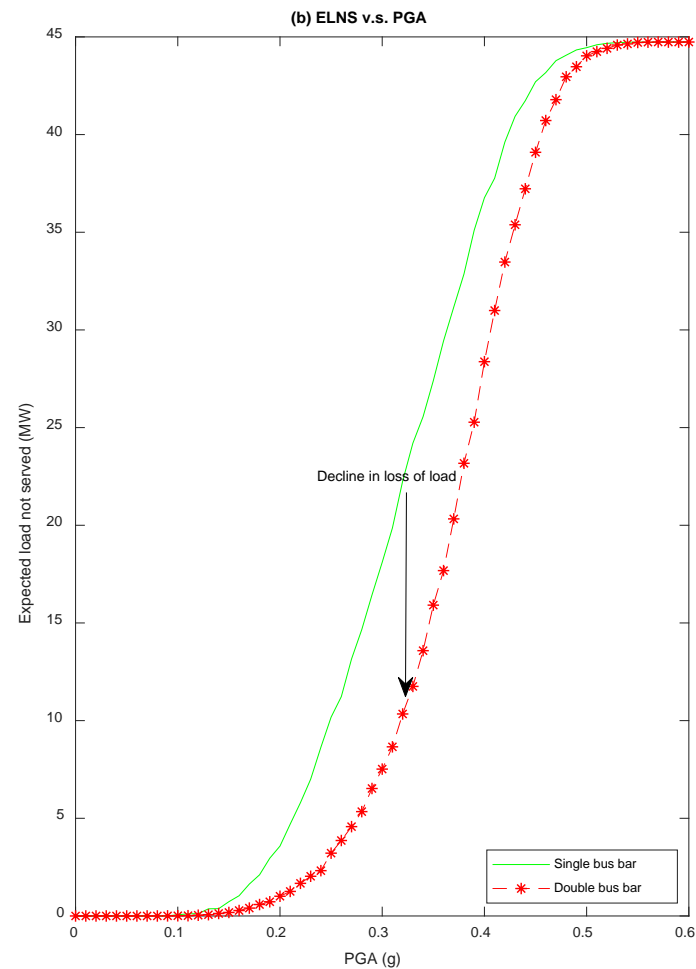

Figure 3.18 Probability density curve of North America blackout from 1996 to 2002

Case study – Comparison of substation configuration

Case study – Comparison of substation configuration

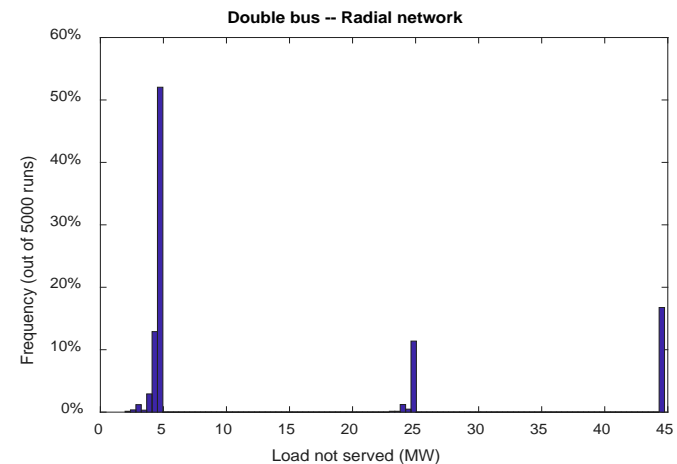

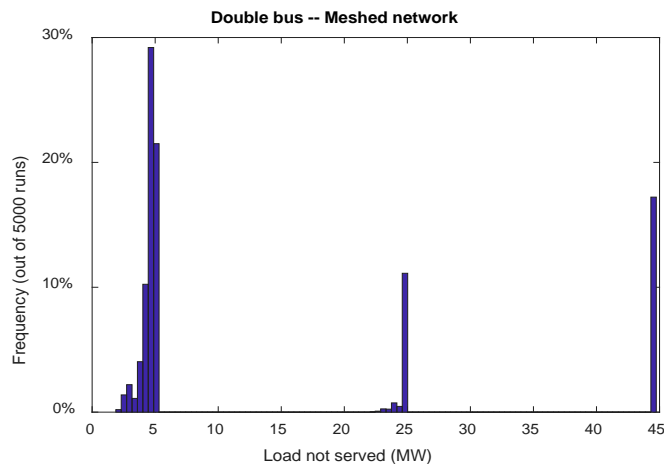

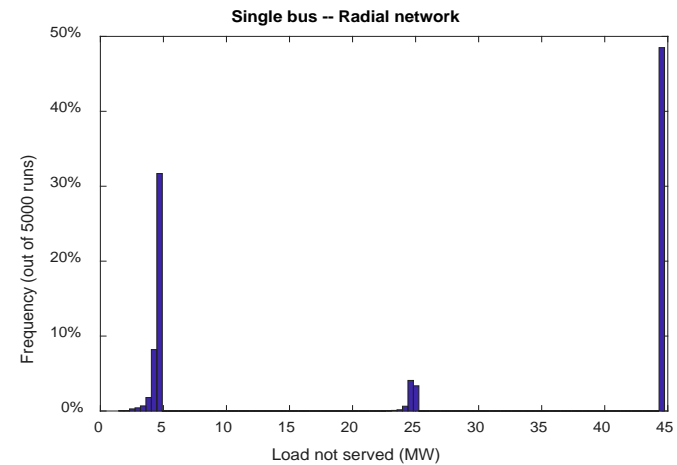

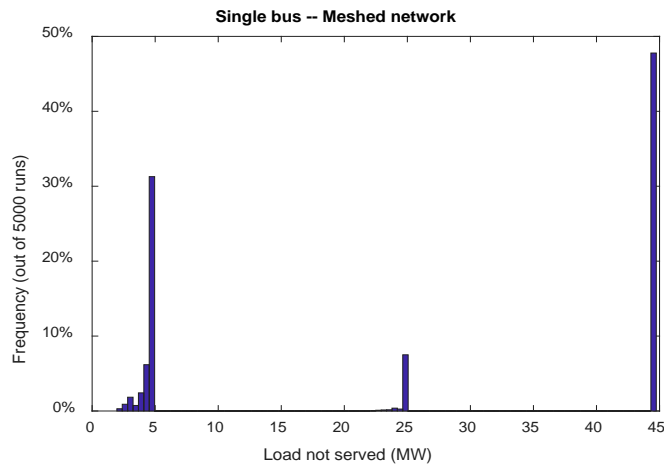

Case study – Comparison of substation configuration

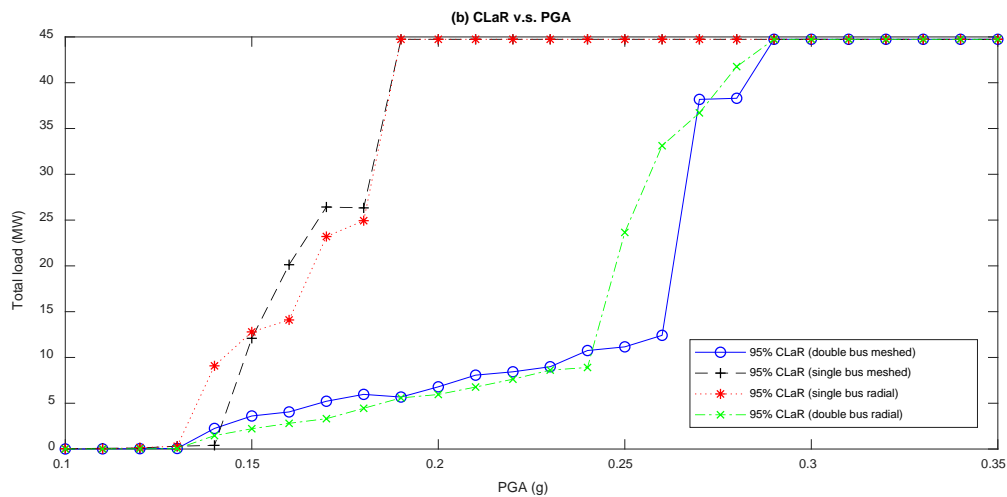

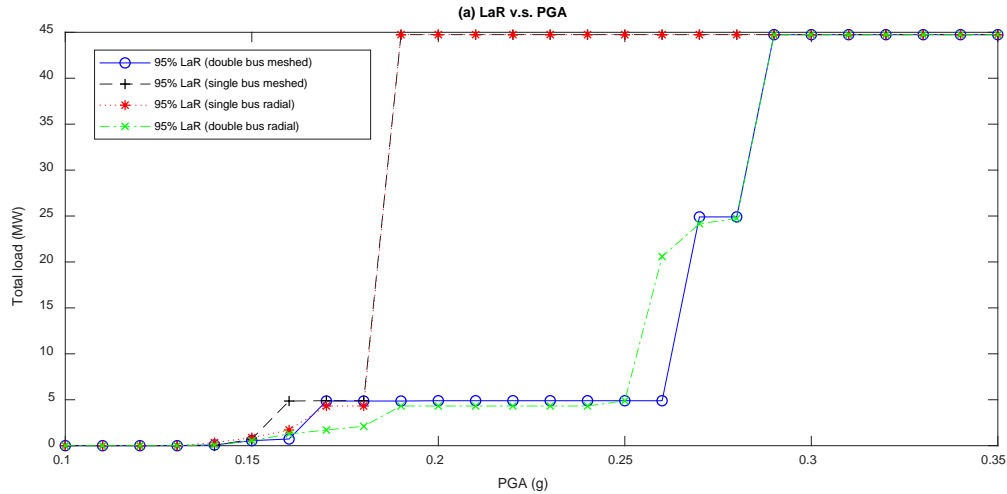

Case study – Comparison of network configuration

Case study – Comparison of network configuration

Case study – Comparison of network configuration

Outline

- Framework
- Approach
- Case study
- Conclusion and outlook

Conclusion and outlook

- Quantification of network level of functionality using network process modelling
- Assessment of the effect of component fragility, network topology and substation configuration
- Future work
 - Recovery process determined by operational decisions and network interdependencies
 - Addition of temporal characteristics will enable resilience quantification

Thanks
